Abstract

Background. Diabetes is one of the most common metabolic diseases that disrupt the functioning of different body organs, including oral tissue. Some diabetic complications remain even after the control of the hyperglycemic condition. The adverse effect of hyperglycaemia on the pulp structure and function has been shown previously.

Objectives. The purpose of this study was to investigate the effect of the hyperglycemic state on the aging of pulp cells and evaluate the role of Wnt signaling as the underlying mechanism of this process.

Material and methods. The isolated pulp cells were cultured in the Minimum Essential Medium (MEM)-alpha for 7, 14 and 21 days under the influence of glucose at concentrations of 5 mM, 20 mM and 30 mM. The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was used to evaluate cell viability, the beta-galactosidase test was applied to assess cellular senescence and gene expression was measured with quantitative real-time polymerase chain reaction (qRT-PCR).

Results. The results of this study showed that cell proliferation decreased following exposure to 20 and 30 mM glucose, which was accompanied by an increased number of senescent cells and an increased p21 expression. There was a significant increase in beta-catenin and Wnt1 expression in response to high glucose. Treatment with beta-catenin inducer enhanced cellular aging in the hyperglycemic state, while beta-catenin inhibitor decreased the senescence response.

Conclusions. The present study further confirmed the effect of the high-glucose condition on pulp cell aging and suggests a role for beta-catenin in the induction of cellular aging. Targeting the key regulators of cellular aging in pulp tissue might lead to the development of new therapies for the prevention and treatment of endodontic complications in diabetic patients.

Key words: Wnt signaling, beta-catenin, pulp stem cells, diabetes, senescence
**Introduction**

Diabetes is among the most common metabolic diseases in the world, being responsible for millions of deaths per year. Diabetes is not only recognized as a disease, but also as a series of diseases that may affect the body's systems and many organs. The global prevalence of diabetes in 2010 was 8.3%, representing 387 million patients; the number is estimated to reach 552 million by 2030. Impaired insulin secretion and function are typical features of the diabetic state, which is characterized by high blood glucose. Diabetes-induced changes in the metabolism of carbohydrates and lipids cause extensive modifications in the function and structure of the vascular and nervous systems, which consequently affect various organs, such as the heart, kidney, eyes, etc.

A large number of studies have shown the influence of high glucose on oral tissue. People with diabetes are at higher risk of periodontal disease than healthy people. Indeed, diabetes has been identified as a major risk factor for periodontitis and gingivitis. Other oral manifestations and complications of diabetes include salivary dysfunction, taste disturbance, increased prevalence of oral mucosa lesions, and poor wound healing capacity. There are also profound changes in the alveolar bone function, accompanied by reduced osteogenic capacity and bone remodeling, which could lead to tooth loss. Studies on the adverse effects of diabetes on pulp tissue are limited. Based on histopathological observations, diabetic pulp undergoes significant changes, including increasing the basement membrane thickness, decreasing the lumen diameter and obliterator endarteritis, contributing to poor vasculature and a higher risk of pulp necrosis. Also, calcifications in diabetic pulp are frequently observed, resembling age-associated changes in old individuals. At the cellular level, hyperglycemia may enhance the expression of inflammatory factors and structural proteins, such as collagen and osteopontin, which is accompanied by an increase in the expression of oxidative stress-related enzymes. Mesenchymal stem cells (MSCs) residing in human pulp exhibit a high capacity of proliferation and odontoblastic differentiation, which was found to be reduced in diabetic rats, thus affecting the regeneration of dentin and the formation of the dentin bridge. Still, the underlying mechanism of hyperglycemia-induced cellular and molecular changes in pulp tissue has not been fully elucidated. There is evidence showing the causative effect of hyperglycemia in the induction of cellular aging in different cell types as well as diabetic models.

Understanding the detailed molecular mechanism of diabetic-induced changes in the cell function and targeting the key regulatory factors can be of great importance in the development of new therapeutic approaches in endodontic treatment for patients suffering from diabetes. In the present study, the effect of high glucose on the induction of the senescence response in cultured pulp cells was investigated. Also, the potential role of Wnt signaling in high glucose-induced senescence was evaluated.

**Material and methods**

**Material**

Glucose was purchased from Merck (CAS 77938-63-7; Darmstadt, Germany). The inhibitor of Wnt/beta-catenin pathway PNU-74654 (CAS 113906-27-7) was from Santa Cruz Biotechnology (Santa Cruz, USA), and both 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-Gal) were from Roche Diagnostics (Mannheim, Germany). Lithium chloride (LiCl; CAS 7447-41-8), magnesium chloride (MgCl2), potassium ferrocyanide (K4[Fe(CN)6]), potassium hexacyanoferrate (II) trihydrate (K4[Fe(CN)6·3H2O]), and dimethyl sulfoxide (DMSO) were purchased from Merck. Fetal bovine serum (FBS) and phosphate-buffered saline (PBS) were from Biowest (Nuaille, France). The sources of all other materials used in the experiments were indicated in the text.

**Primary cell culture, stem cell characterization and cell treatment**

Pulp cells were isolated from dental pulp tissue. For this aim, the teeth extracted from 3 healthy patients attending the Dental Policlinic of Tehran University of Medical Sciences in Iran were transferred immediately to the laboratory in Minimum Essential Medium (MEM)-alpha (Biowest) with 20 mM 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES) buffer, pH 7.4. Informed written consent was obtained from the subjects for conducting the study. The tissues were digested in the collagenase-dispase enzyme solution (Invitrogen, Waltham, USA) and the primary cells were isolated according to the previously reported method. The isolated cells were cultured in MEM-alpha supplemented with 10% FBS under the humidified condition at 37°C with 5% CO2. The pulp cells were characterized by the expression of their surface cluster of differentiation (CD) markers and their potential to differentiate into different cell lineages according to the previously described techniques.

To study the effect of glucose on pulp cells, a stock solution of 100 mg/mL glucose was prepared in MEM-alpha. The solution was filtered and the appropriate volume was added to each well containing the culture medium to give the total concentrations of 20 mM and 30 mM glucose. The pulp cells were treated with the medium containing 20 mM or 30 mM glucose for 7, 14 and 21 days. The control groups were treated with 5 mM glucose. The medium was refreshed every 3 days. The cells were exposed to LiCl (6 mM) or PNU-74654 (10 µM) on the same day of glucose treatment.
MTT assay

The cells were seeded in 96-well tissue culture plates at a density of 4,000 cells/well. After overnight rest time, the cells were treated with different concentrations of glucose in MEM-alpha supplemented with FBS. Cell proliferation was measured with the MTT assay, which is based on the cleavage of the tetrazolium salt (MTT) by metabolically active cells to form the purple formazan crystal dye. After removing the cell culture medium from each well, 100 µL of the MTT solution (50 µg/10 mL PBS) was added and the plate was incubated at 37°C for 3–4 h. Following the formation of formazan crystals, the MTT solution was substituted with 50 µL of DMSO to dissolve the crystals while shaking for 20 min. The absorbance was measured at wavelengths of 570 nm and 650 nm by means of a multi-well spectrophotometer (BioTek Instruments, Inc., Winooski, USA).

Beta-galactosidase assay

Beta-galactosidase cytochemical staining was used to evaluate cellular senescence. The beta-galactosidase enzyme is expressed in the lysosomes of all cells at pH 4, which is the optimum pH of the enzyme activity. The senescent cells with high beta-galactosidase activity are distinguished under high pH 6. For this experiment, the cultured cells in 24-well plates were washed with PBS and fixed with paraformaldehyde 2% in PBS for 5 min, which was followed by washing with PBS twice. The senescence-associated (SA)-beta-galactosidase staining solution was prepared in PBS containing MgCl2 (2 mM), K4[Fe(CN)6·3H2O] (2.12 mg/mL), K3[Fe(CN)6] (1.64 mg/mL), and X-Gal (1 mg/mL) at pH 6. The 500 µL of the solution was added to each well and the plate was incubated at 37°C. After 24 h, the staining solution was removed and the cells were rinsed twice in PBS. Finally, 500 µL of the SYBR® green solution (1:10,000) (Sigma-Aldrich, St. Louis, USA) was added to each well. The blue X-Gal-stained cells were counted under light microscopy (Leica Camera, Wetzlar, Germany). The number of blue cells was recorded in at least 10 different microscopic fields and the percentages were calculated from the total number of fluorescent nuclei that were detected in the same field under fluorescence microscopy.17

Real-time polymerase chain reaction and gene expression assessment

Total RNA was extracted from the control and treated samples with the use of TRI Reagent® (Sigma-Aldrich), with standard procedures based on phenol-chloroform extraction and ethanol precipitation. The extracted RNA was quality-controlled for purity and integrity with agarose gel electrophoresis and the measurement of the 260/280 nm ratio of absorbance. Next, 1 µg of RNA was treated with 0.1 U of RNase-free DNase I (Roche Applied Science, Mannheim, Germany) and converted to cDNA, using BioFact™ RT-Kit (BIOFACT, Daejeon, South Korea) according to the manufacturer’s protocol. Subsequently, 2 µL of cDNA was used as a template for quantitative real-time polymerase chain reaction (qRT-PCR) with 1 µL of primers, 10 µL of BioFact™ 2X Real-Time PCR Master Mix and 1 µL of random hexamer, and 6 µL of sterile, diethyl pyrocarbonate (DEPC)-treated water. The conditions for qRT-PCR include: 15 min at 95°C for denaturation; 20 s at 95°C; 20 s at 60°C; and 30 s at 72°C.

The sequence of primers was as follows:
P21 F 5´-GGCACCCCTAGTCTACCTCA-3´, R 5´-CTCCTTGTTCGCCGCTGTAAT-3´;
Wnt-1 F 5´-GTTCCATCGAAATCTGCAAGG-3´, R 5´-CTGCCTCTGTTGTGAAGG-3´;
beta-cat F 5´-TCCCTCACTGCAAACTGCT-3´, R 5´-CACCATCTGAGGAGAACGCAT-3´; and
GAPDH F 5´-CACATGGCCTCCAAGGAGTAA-3´, R 5´-TGAGGGTCTCTTCTTCTTG-3´.

The PCR products were visualized on 1% agarose gel and melting curves were evaluated for single peaks. The relative fold change was calculated relative to the control group after normalization to the internal control gene, glyceraldehyde 3-phosphate dehydrogenase (GAPDH). The formula 2−ΔΔCt was applied as the standard method for determining gene expression changes.

Statistical analysis

The significance of the obtained data was determined using two-way analysis of variance (ANOVA) followed by Tukey’s multiple comparison test with the help of the IBM SPSS Statistics for Windows software, v. 20.0 (IBM Corp., Armonk, USA). All the experiments were performed at least twice, each in triplicate on separate dates. The level of significance was set at 0.05.

Results

Characterization of pulp mesenchymal stem cells

The extracted pulp MSCs successfully adhered to the plastic cell culture plates and were positive for MSC surface markers CD73, CD90 and CD105, as assessed by flow cytometry and the immunofluorescence analysis (Fig. 1A,1B). Also, the cells showed the lack of the expression of hematopoietic markers CD 45 and CD 34. The MSCs could differentiate into different cell types, including the osteogenic, adipogenic and chondrogenic lineages (Fig. 1C).
High glucose reduced the proliferation of pulp cells

The proliferation rate of the isolated pulp cells was examined at a high concentration of glucose during long-term exposure by means of the MTT assay. The results showed that while the number of cells in the control group (5 mM glucose) increased continuously, exposure to 20 mM and 30 mM glucose significantly inhibited cells proliferation on days 14 and 21 (Fig. 2A).
High glucose induced cellular senescence in pulp cells

To evaluate the presence of the senescent cells among the pulp cells treated with glucose, the beta-galactosidase assay was performed. The results showed that exposure to high concentrations of glucose increased SA beta-galactosidase activity in a dose-dependent manner (Fig. 2B, 2C). The number of aging cells increased with the passing time and an increasing glucose concentration. To further confirm the senescence response, the expression of the p21 marker associated with cell cycle arrest was assessed. High glucose resulted in an enhanced expression of p21 after 7-, 14-, and 21-day exposure (Fig. 3).

Increased beta-catenin and Wnt1 expression at high glucose

There was a significant increase in the expression of beta-catenin at 30 mM glucose as compared to control 5 mM glucose on day 7 ($p < 0.001$). Exposure to 20 mM and 30 mM glucose enhanced Wnt1 expression in the cultured pulp cells (Fig. 4).

High glucose-induced senescence response is mediated by beta-catenin

To evaluate the role of Wnt signaling in the glucose-induced senescence response, the cells were treated with beta-catenin inhibitor – PNU-74654 – and beta-catenin inducer – LiCl. The results showed that LiCl aggravated cellular senescence in the presence of high concentrations of glucose (20 mM and 30 mM). Also, an increased percentage of senescent cells alleviated in the presence of PNU-74654 (10 µM) at high glucose concentrations (Fig. 5A). Similarly, LiCl induced p21 expression, while exposure to PNU-74654 reduced the p21 level under hyperglycemic conditions, as measured by qRT-PCR (Fig. 5B).
Discussion

Senescence or cellular aging is a process that irreversibly ceases the proliferation of normal cells in response to external environmental factors or internal stimuli, such as telomere length shortening and oncogene induction. While maintaining their metabolic activity, the senescent cells undergo phenotypic changes in their structure and secretory profile. In this study, we attempted to investigate the influence of high glucose on cells isolated from pulp tissue in an in vitro model resembling the hyperglycemic condition in diabetic patients.

Considering that the fasting blood glucose of diabetic patients rises above 10 mM, in the present study – in order to simulate the diabetic state – the concentrations of 20 mM and 30 mM were used, in accordance with the concentrations applied in previous studies.18–20 The optimum concentration of 5 mM in the cell culture medium was selected as the control group. Our results showed that the culture medium enriched with glucose could pose an inhibitory effect on the proliferation rate after 2 and 3 weeks of exposure, indicating the chronic influence of the hyperglycemic medium.

Beta-galactosidase staining method is regarded as the key test for the evaluation of cellular aging based on the level of lysosomal beta-galactosidase activity at pH 6.21 Our results showed that the number of beta-galactosidase-positive cells increased at the 20 mM and 30 mM glucose concentrations as compared to the control group. Along with beta-galactosidase activity, the expression of cyclin-dependent kinase (CDK) inhibitor p21 – the marker of cellular senescence – was increased. The data further confirmed the induction of senescence and cell cycle arrest during long-time exposure to the hyperglycemic condition.
Human pulp tissue has a key role in the maintenance and repair of the teeth. It is comprised of the stromal cell population with a high capacity of differentiation into odontoblasts—the main functional cells in dentin regeneration.\textsuperscript{22} Previous studies in animal models have shown the association between diabetes and reduced pulp healing capacity.\textsuperscript{11} Also, few studies are available on bone marrow-derived stem cells, and the adverse effect of hyperglycemia on their proliferation and differentiation.\textsuperscript{23,24} Similarly, our results, Oancea et al.\textsuperscript{25} and Yan et al.\textsuperscript{26} also revealed the disturbance of dental pulp cell proliferation at high glucose. Recent research indicates that the exposure of bone marrow-derived hematopoietic stem cells to a high glucose-containing medium induces aging, genetic instability and telomere length changes in these cells.\textsuperscript{27} However, the precise mechanism of aging induction in these cells remains unclear. There is also further evidence on glucose-induced bone marrow-derived stem cell senescence and the causative role of oxidative-mediated autophagy.\textsuperscript{20} While less has been reported on the senescence response in diabetic pulp tissue or cultured pulp cells, our results clearly showed the induction of cellular aging in the cultured pulp cells exposed to long-term hyperglycemic conditions.

Searching for the underlying molecular mechanism, we observed the stimulation of the expression of Wnt1 and beta-catenin. Thereby, it hinted the involvement of the Wnt signaling pathway in glucose-induced pulp cell senescence. Indeed, the Wnt/beta-catenin signaling pathway plays an important role in various cellular processes, such as proliferation, differentiation, migration, survival, apoptosis, and pluripotency.\textsuperscript{28,29} The Wnt signaling pathway comprises both the canonical-beta-catenin dependent and the non-canonical-beta-catenin independent pathways, and it is believed that the canonical pathway plays a key role in dentinogenesis and dentin regeneration.\textsuperscript{24} In the presence of Wnt ligand and binding to specific cell membrane receptors, cytoplasmic beta-catenin protein is transferred to the nucleus and activates the transcription of many target genes. In the present study, we applied PNU-74564, the binder of beta-catenin, to inhibit the Wnt signaling pathway.\textsuperscript{30} Lithium chloride is also known for its role in stabilizing beta-catenin through the inhibition of glycosyn thase kinase 3 beta (GSK3β) activity, and therefore the activation of canonical Wnt signaling.\textsuperscript{31} Our results demonstrated that in the presence of beta-catenin inhibitor, the percentage of the senescent cells was reduced, while LiCl significantly enhanced glucose-induced senescence. The data further confirmed the involvement of Wnt signaling, particularly beta-catenin, in the progression of diabetic-induced cellular aging. Regarding the association between Wnt signaling and senescence, Liu et al. through in vitro and in vivo studies revealed that the activation of canonical Wnt-signaling triggers senescence in primary mouse embryonic fibroblasts and epithelial cells.\textsuperscript{32} Another study on thymocytes showed that the transgenic expression of beta-catenin induces cell growth arrest, DNA damage and senescence.\textsuperscript{33} Also, bone marrow-derived stem cells from systemic lupus erythematosus patients exhibited signs of senescence and showed high activity of beta-catenin.\textsuperscript{34} Although there are some other studies which indicate the role of beta-catenin in the induction of cell proliferation.\textsuperscript{35,36}

Further detailed clinical studies are essential to assess the pulp tissue proliferation rate and the level of beta-catenin in diabetic patients. Based on the current results, Wnt signaling might be the potential target for the inhibition of the senescence response in the hyperglycemic condition, suggesting the development of bioactive materials in pulp capping that would be specific for diabetic patients.

**Conclusions**

The results of the present study showed that the diabetic condition disturbed pulp cell proliferation and induced the senescence phenotype, which is mediated by beta-catenin/Wnt signaling. Such changes might compromise the healing and regenerative capacity of diabetic pulp. Based on the results of the current study and previous research, it is suggested that differential approaches in endodontic treatment need to be considered for diabetic pulp. Knowledge on the molecular mechanism of diabetic-induced senescence and targeting the key regulatory protein will help us find new therapeutic approaches in endodontic treatment for diabetic patients.
